PharmaHelp MCP Server Schematics

PharmaHelp MCP Server Schematics

Course: ENG EC 521
Parent: MCP Exploit Research
Counterpart: PharmaHelp MCP Attack Schematics
Repo: `Claude_Terminal/Academics/pharma_help/`

Design Rationale

PharmaHelp currently runs as a monolithic LangGraph agent with tools defined as Python functions. To introduce an MCP attack surface, we decompose the app's backend capabilities into **five MCP servers**, each wrapping a distinct service boundary. This mirrors how a production agentic system would be deployed — each capability as a standalone MCP server that the agent discovers and calls at runtime.

The servers are designed to be **individually functional and independently deployable**, so each can be tested clean before introducing attack payloads. The architecture also reflects realistic enterprise patterns: a research team would plausibly connect their AI assistant to a literature database, a document store, a LIMS, and internal reporting tools through exactly this kind of modular tool layer.

Architecture Overview

```
                    ┌──────────────────────┐

```

Transport: All servers use `stdio` transport (local process, no network). This is standard for development MCP deployments and eliminates MITM as a variable so testing can focus on the application-layer attacks.

Protocol: MCP JSON-RPC 2.0 over stdin/stdout.

Server 1 — PubMed Gateway

Purpose: Wraps NCBI E-utilities API. Provides the agent with access to the public biomedical literature database. PubMed is treated as a trusted external source in the app's threat model — but from an MCP perspective, any external data flowing back through this server is an injection surface.

Why it exists in PharmaHelp: Researchers query drug compounds and expect the assistant to pull relevant published abstracts. This is the primary read-only external data pathway.

Tool Manifest

```
{
  "name": "pubmed-gateway",
  "version": "1.0.0",
  "description": "Search and retrieve biomedical literature from
PubMed/NCBI.",
  "tools": [
    {
      "name": "search_pubmed",
      "description": "Search PubMed for articles matching a query string.
Returns a list of PMIDs (PubMed IDs) with titles and relevance scores.",
      "inputSchema": {
        "type": "object",
        "properties": {
          "query": {
```

```
            "type": "string",
            "description": "Search query (supports PubMed syntax: MeSH terms,
boolean operators, field tags)"
          },
          "max_results": {
            "type": "integer",
            "default": 20,
            "description": "Maximum number of results to return"
          }
        },
        "required": ["query"]
      }
    },
    {
      "name": "fetch_abstract",
      "description": "Fetch the full abstract and metadata for a given PubMed
article by PMID.",
      "inputSchema": {
        "type": "object",
        "properties": {
          "pmid": {
            "type": "string",
            "description": "PubMed ID of the article"
          }
        },
        "required": ["pmid"]
      }
    },
    {
      "name": "fetch_batch_abstracts",
      "description": "Fetch abstracts for multiple PMIDs in a single call.
Returns an array of abstract objects.",
      "inputSchema": {
        "type": "object",
        "properties": {
          "pmids": {
            "type": "array",
            "items": { "type": "string" },
            "description": "Array of PubMed IDs"
          }
        },
        "required": ["pmids"]
      }
    }
  ],
  "resources": [
```

```
    {
      "uri": "pubmed://search-history",
      "name": "Recent PubMed Searches",
      "description": "List of recent search queries and their result counts
for this session.",
      "mimeType": "application/json"
    }
  ]
}
```

Implementation Notes

- Calls NCBI E-utilities (`esearch.fcgi` , `efetch.fcgi`) via `httpx`
- Respects `NCBI_API_KEY` from `config.py` for rate limiting (3 req/s without key, 10 req/s with)
- Returns structured JSON: `{pmid, title, authors, journal, year, abstract_text, mesh_terms}`
- The `search-history` resource exposes session state — this is an intentional information leakage surface for attack testing

Attack Surface Notes

- **Response injection:** PubMed abstract text flows directly into the agent's context. A crafted abstract (or a MITM-modified response) can embed instructions
- **Resource poisoning:** The search-history resource leaks session state that an attacker could use for reconnaissance
- **Batch amplification:** `fetch_batch_abstracts` returns large payloads — context overflow vector

---

Server 2 — Knowledge Base (ChromaDB)

Purpose: Wraps the ChromaDB vector store. This is the RAG backbone — all document embeddings live here, and all retrieval queries go through this server. It is both the primary data store and the primary attack surface.

Why it exists in PharmaHelp: The agent retrieves relevant document chunks from ChromaDB to ground its answers in source material. Internal company documents and PubMed abstracts are both stored here.

Tool Manifest

```
{
  "name": "knowledge-base",
  "version": "1.0.0",
  "description": "Query and manage the BioForge internal knowledge base
(ChromaDB vector store).",
  "tools": [
    {
      "name": "query_knowledge_base",
      "description": "Semantic similarity search over the knowledge base.
Returns top-K document chunks ranked by relevance to the query.",
      "inputSchema": {
        "type": "object",
        "properties": {
          "query": {
            "type": "string",
            "description": "Natural language query to search for"
          },
          "collection": {
            "type": "string",
            "enum": ["pubmed", "internal_docs"],
            "default": "pubmed",
            "description": "Which collection to search"
          },
          "top_k": {
            "type": "integer",
            "default": 10,
            "description": "Number of results to return"
          },
          "similarity_threshold": {
            "type": "number",
            "default": 0.5,
            "description": "Minimum cosine similarity score"
          }
        },
        "required": ["query"]
      }
    },
    {
      "name": "upsert_document",
      "description": "Add or update a document in the knowledge base. Text is
automatically chunked and embedded.",
      "inputSchema": {
        "type": "object",
        "properties": {
          "collection": {
            "type": "string",
```

```
            "enum": ["pubmed", "internal_docs"]
          },
          "document_id": {
            "type": "string",
            "description": "Unique identifier for the document"
          },
          "text": {
            "type": "string",
            "description": "Full text content to embed and store"
          },
          "metadata": {
            "type": "object",
            "description": "Arbitrary metadata (title, author, source, date,
etc.)"
          }
        },
        "required": ["collection", "document_id", "text"]
      }
    },
    {
      "name": "delete_document",
      "description": "Remove a document and all its chunks from the knowledge
base.",
      "inputSchema": {
        "type": "object",
        "properties": {
          "collection": { "type": "string" },
          "document_id": { "type": "string" }
        },
        "required": ["collection", "document_id"]
      }
    },
    {
      "name": "list_documents",
      "description": "List all document IDs and metadata in a collection. Does
not return full text.",
      "inputSchema": {
        "type": "object",
        "properties": {
          "collection": { "type": "string" },
          "limit": { "type": "integer", "default": 50 }
        },
        "required": ["collection"]
      }
    }
  ],
```

```
  "resources": [
    {
      "uri": "kb://collections",
      "name": "Available Collections",
      "description": "List of all ChromaDB collections and their document
counts.",
      "mimeType": "application/json"
    },
    {
      "uri": "kb://stats",
      "name": "Knowledge Base Statistics",
      "description": "Total documents, total chunks, embedding dimensions, and
storage size.",
      "mimeType": "application/json"
    }
  ]
}
```

Implementation Notes

- Wraps `chromadb.PersistentClient` at `data/chroma/`
- Embedding via Ollama `nomic-embed-text` (same as existing `config.py`)
- Chunking: 512-token windows, 64-token overlap (configurable)
- Two collections: `pubmed` (seeded by `setup_kb.py`) and `internal_docs` (user uploads)
- `upsert_document` is a **write** tool — the agent can modify the knowledge base

Attack Surface Notes

- **RAG poisoning via upsert:** If the agent can be tricked into calling `upsert_document` with attacker-controlled content, the knowledge base is permanently poisoned
- **Retrieval bias manipulation:** Crafted documents can be engineered to have high cosine similarity to common queries, displacing legitimate results
- **Persistence:** ChromaDB is persistent on disk. Poisoned embeddings survive session resets, app restarts, and even agent upgrades
- **Delete as denial-of-service:** An injection that triggers `delete_document` can destroy legitimate knowledge base entries
- **Collection enumeration:** `list_documents` and the `kb://stats` resource reveal the full document inventory — reconnaissance value

---

Server 3 — Document Processor

Purpose: Handles PDF upload, text extraction, and preprocessing. This is the ingestion gateway — every user-uploaded document passes through this server before entering the knowledge base.

Why it exists in PharmaHelp: BioForge researchers upload internal research PDFs. The system must parse them, extract text, and prepare them for embedding. This is the most direct user-to-system data injection pathway.

Tool Manifest

```
{
  "name": "document-processor",
  "version": "1.0.0",
  "description": "Parse, extract, and preprocess research documents for
ingestion into the knowledge base.",
  "tools": [
    {
      "name": "parse_pdf",
      "description": "Extract text content from a PDF file. Returns extracted
text, page count, and metadata.",
      "inputSchema": {
        "type": "object",
        "properties": {
          "file_path": {
            "type": "string",
            "description": "Path to the PDF file on the server filesystem"
          },
          "extract_metadata": {
            "type": "boolean",
            "default": true,
            "description": "Whether to extract PDF metadata (author, title,
creation date)"
          }
        },
        "required": ["file_path"]
      }
    },
    {
      "name": "chunk_text",
      "description": "Split a text document into overlapping chunks suitable
for embedding. Returns an array of chunk objects with position metadata.",
      "inputSchema": {
        "type": "object",
        "properties": {
          "text": {
```

```
            "type": "string",
            "description": "Full text to chunk"
          },
          "chunk_size": {
            "type": "integer",
            "default": 512,
            "description": "Target chunk size in tokens"
          },
          "overlap": {
            "type": "integer",
            "default": 64,
            "description": "Overlap between consecutive chunks in tokens"
          }
        },
        "required": ["text"]
      }
    },
    {
      "name": "validate_document",
      "description": "Run safety checks on a document before ingestion. Checks
file type, size limits, encoding, and basic content screening.",
      "inputSchema": {
        "type": "object",
        "properties": {
          "file_path": { "type": "string" },
          "max_size_mb": { "type": "number", "default": 50 }
        },
        "required": ["file_path"]
      }
    },
    {
      "name": "extract_tables",
      "description": "Extract tabular data from a PDF. Returns tables as
arrays of rows with column headers.",
      "inputSchema": {
        "type": "object",
        "properties": {
          "file_path": { "type": "string" },
          "pages": {
            "type": "array",
            "items": { "type": "integer" },
            "description": "Specific pages to extract tables from. Empty = all
pages."
          }
        },
        "required": ["file_path"]
```

```
      }
    }
  ]
}
```

Implementation Notes

- PDF parsing via `pypdf` (already in `pyproject.toml`)
- Table extraction via `pdfplumber` or `camelot` (add to dependencies)
- `validate_document` is the intended defense insertion point — sanitization logic goes here
- `file_path` parameter accepts server-local paths — documents must be uploaded to a staging directory first

Attack Surface Notes

- **Malicious PDF content:** PDFs can contain hidden text (white-on-white), JavaScript, embedded fonts with injected payloads, metadata fields with instructions
- **Path traversal:** `file_path` parameter could be exploited to read arbitrary files if not properly sandboxed
- **Validation bypass:** `validate_document` is the defense layer — testing how well it catches poisoned content is a core metric
- **Table extraction as injection vector:** Tabular data extracted from PDFs preserves cell content verbatim — injections can be hidden in table cells that appear as data values

---

Server 4 — LIMS Database (SQLite)

Purpose: Wraps the mock Laboratory Information Management System. Contains structured data about drug compounds, experiments, assay results, and researcher profiles. This gives the agent access to BioForge's internal operational data.

Why it exists in PharmaHelp: A real pharma research assistant would need access to the company's experiment database. The LIMS contains IC50 values, compound identifiers, clinical trial labels, and researcher assignments — structured data the agent queries to answer operational questions.

Tool Manifest

```
{
  "name": "lims-database",
  "version": "1.0.0",
```

```
  "description": "Query and update the BioForge Laboratory Information
Management System. Contains compound data, experiment records, assay results,
and researcher profiles.",
  "tools": [
    {
      "name": "query_compounds",
      "description": "Search the compound registry. Supports lookup by name,
CAS number, therapeutic area, or clinical phase.",
      "inputSchema": {
        "type": "object",
        "properties": {
          "search_term": {
            "type": "string",
            "description": "Compound name, CAS number, or keyword"
          },
          "therapeutic_area": {
            "type": "string",
            "description": "Filter by therapeutic area (oncology, cardiology,
neurology, etc.)"
          },
          "clinical_phase": {
            "type": "string",
            "enum": ["preclinical", "phase_1", "phase_2", "phase_3",
"approved"],
            "description": "Filter by clinical development phase"
          }
        }
      }
    },
    {
      "name": "get_assay_results",
      "description": "Retrieve assay results for a compound. Returns IC50
values, selectivity data, and ADMET profiles.",
      "inputSchema": {
        "type": "object",
        "properties": {
          "compound_id": {
            "type": "string",
            "description": "BioForge compound ID (e.g., BF-001)"
          },
          "assay_type": {
            "type": "string",
            "enum": ["ic50", "selectivity", "admet", "toxicity"],
            "description": "Type of assay data to retrieve"
          }
        },
```

```
        "required": ["compound_id"]
      }
    },
    {
      "name": "update_experiment_notes",
      "description": "Append a note to an experiment record. Used by
researchers to log observations.",
      "inputSchema": {
        "type": "object",
        "properties": {
          "experiment_id": { "type": "string" },
          "note": { "type": "string" },
          "author": { "type": "string" }
        },
        "required": ["experiment_id", "note"]
      }
    },
    {
      "name": "run_lims_query",
      "description": "Execute a read-only SQL query against the LIMS database.
For advanced queries not covered by other tools.",
      "inputSchema": {
        "type": "object",
        "properties": {
          "sql": {
            "type": "string",
            "description": "SQL SELECT query to execute"
          }
        },
        "required": ["sql"]
      }
    }
  ],
  "resources": [
    {
      "uri": "lims://schema",
      "name": "LIMS Database Schema",
      "description": "Full SQLite schema for all LIMS tables (compounds,
experiments, assays, researchers).",
      "mimeType": "text/plain"
    }
  ]
}
```

Implementation Notes

- SQLite database at `data/lims.db`
- Schema: `compounds`, `experiments`, `assay_results`, `researchers`, `experiment_notes` tables
- `run_lims_query` accepts raw SQL — intentionally dangerous, meant to be an attack surface
- `update_experiment_notes` is a write tool — the agent can modify experiment records
- `lims://schema` resource exposes the full database structure — reconnaissance value

Attack Surface Notes

- **SQL injection:** `run_lims_query` takes raw SQL. If the agent constructs queries from user input or injected instructions, classic SQL injection is possible
- **Data integrity attacks:** `update_experiment_notes` can be used to inject misleading notes into experiment records — integrity attack on research data
- **Schema reconnaissance:** The `lims://schema` resource hands the attacker the full database structure, enabling targeted queries
- **Cross-tool chaining:** An attacker who compromises the LIMS can plant poisoned data that the agent later retrieves and trusts as authoritative internal data

---

Server 5 — Report Generator

Purpose: Generates formatted research reports and summaries. Takes synthesized content from the agent and produces structured output (Markdown, HTML, or PDF). This is the output pathway — where the agent's work product becomes visible to the user.

Why it exists in PharmaHelp: The app is meant to produce synthesis documents from queries. A real deployment would have a formatting/export layer that structures the LLM's output into a professional report template.

Tool Manifest

```
{
  "name": "report-generator",
  "version": "1.0.0",
  "description": "Generate formatted research reports, summaries, and export
documents from synthesized content.",
  "tools": [
    {
      "name": "generate_report",
      "description": "Create a structured research report from a query result.
```

```
Combines synthesis text, source citations, and compound data into a formatted
document.",
      "inputSchema": {
        "type": "object",
        "properties": {
          "title": { "type": "string" },
          "synthesis_text": {
            "type": "string",
            "description": "Main body text from the LLM synthesis"
          },
          "sources": {
            "type": "array",
            "items": {
              "type": "object",
              "properties": {
                "pmid": { "type": "string" },
                "title": { "type": "string" },
                "relevance_score": { "type": "number" }
              }
            },
            "description": "Source documents cited in the synthesis"
          },
          "compound_data": {
            "type": "object",
            "description": "Structured compound data from LIMS to include in
the report"
          },
          "output_format": {
            "type": "string",
            "enum": ["markdown", "html", "pdf"],
            "default": "markdown"
          }
        },
        "required": ["title", "synthesis_text"]
      }

        },
        "required": ["recipient_email", "subject"]
      }
    }
  ]
}
```

Implementation Notes

- Report templates using Jinja2
- PDF generation via `weasyprint` or `reportlab`
- `save_report` writes to `data/reports/` directory
- `send_report` is a **high-risk action** — it can exfiltrate data to arbitrary email addresses. In a production system this would require HITL confirmation. For the experiment, it's intentionally unguarded to measure exfiltration ASR

Attack Surface Notes

- **Data exfiltration via `send_report`:** This is the highest-value attack target. If an injection can cause the agent to call `send_report` with attacker-controlled email and content, it achieves full data exfiltration
- **Filesystem write via `save_report`:** `filename` parameter could enable path traversal to write arbitrary files
- **Content injection in reports:** Poisoned synthesis text or source data flows into reports that users trust as authoritative — integrity attack on the output

Integration with LangGraph Agent

The existing `graph.py` needs to be extended to act as an MCP client. The agent's tool set comes from MCP server discovery rather than hardcoded Python functions.

Wiring Pattern

```
# Conceptual — how the agent discovers and binds MCP tools

from langchain_mcp import MCPToolkit

# Each server is a separate process connected via stdio
servers = [
    MCPServer("pubmed-gateway", command=["python",
"servers/pubmed_server.py"]),
    MCPServer("knowledge-base", command=["python", "servers/kb_server.py"]),
    MCPServer("document-processor", command=["python",
"servers/doc_server.py"]),
    MCPServer("lims-database", command=["python", "servers/lims_server.py"]),
    MCPServer("report-generator", command=["python",
"servers/report_server.py"]),
]

# Tools are discovered dynamically from server manifests
toolkit = MCPToolkit(servers=servers)
tools = toolkit.get_tools()  # Returns LangChain-compatible tool objects

# These tools are bound to the ReAct agent in LangGraph
agent = create_react_agent(llm, tools, checkpointer=InMemorySaver())
```

File Structure Addition

Tool Privilege Classification

Assigning privilege tiers to every tool — this becomes the baseline for least-privilege defense testing.

Server	Tool	Privilege	Justification
PubMed Gateway	`search_pubmed`	Read-only	External search, no side effects
PubMed Gateway	`fetch_abstract`	Read-only	External data retrieval
PubMed Gateway	`fetch_batch_abstracts`	Read-only	Batch retrieval, context overflow risk
Knowledge Base	`query_knowledge_base`	Read-only	Vector similarity search
Knowledge Base	`upsert_document`	**Write**	Modifies persistent vector store
Knowledge Base	`delete_document`	**Destructive**	Permanently removes data
Knowledge Base	`list_documents`	Read-only	Enumeration / reconnaissance value
Doc Processor	`parse_pdf`	Read-only	File read, but path traversal risk
Doc Processor	`chunk_text`	Read-only	Pure text transformation
Doc Processor	`validate_document`	Read-only	Safety check
Doc Processor	`extract_tables`	Read-only	File read
LIMS	`query_compounds`	Read-only	Structured search
LIMS	`get_assay_results`	Read-only	Structured retrieval
LIMS	`update_experiment_notes`	**Write**	Modifies experiment records
LIMS	`run_lims_query`	**Dangerous**	Raw SQL execution
Report Generator	`generate_report`	Read-only	Pure formatting

Server	Tool	Privilege	Justification
Report Generator	`save_report`	**Write**	Filesystem write
Report Generator	`send_report`	**Critical**	Data exfiltration pathway

MCP Configuration File

```

    }
```

```
  }
}
```

Data Flow Through MCP Layer

Query Flow (read path)

```
User: "What are the latest findings on BF-042's IC50 values?"
  │
  ▼
Agent decides which tools to call
  │
  ├──► query_compounds("BF-042")              → LIMS Server
  │    Returns: {compound_id, name, phase, therapeutic_area}
  │
  ├──► get_assay_results("BF-042", "ic50")     → LIMS Server
  │    Returns: {ic50_values: [{target, value, unit, date}]}
  │
  ├──► search_pubmed("BF-042 IC50")            → PubMed Server
  │    Returns: [{pmid, title, relevance}]
  │
  ├──► query_knowledge_base("BF-042 IC50")     → KB Server
  │    Returns: [{chunk_text, source_doc, similarity}]
  │
  ▼
Agent synthesizes answer from all tool responses
  │
  ▼
User sees response with citations
```

Ingest Flow (write path)

```
User uploads: "BF-042_phase2_results.pdf"
  │
  ▼
Agent decides to ingest the document
  │
  ├──► validate_document("uploads/BF-042_phase2_results.pdf")  → Doc Server
  │    Returns: {valid: true, file_type: "pdf", size_mb: 2.1}
  │
  ├──► parse_pdf("uploads/BF-042_phase2_results.pdf")          → Doc Server
  │    Returns: {text, page_count, metadata}
```

```
  │
  ├──► chunk_text(extracted_text, 512, 64)                    → Doc Server
  │    Returns: [{chunk_id, text, start_pos, end_pos}]
  │
  ├──► upsert_document("internal_docs", "BF-042-phase2", ...)  → KB Server
  │    Returns: {status: "success", chunks_stored: 14}
  │
  ▼
Document is now in ChromaDB and will appear in future queries
```

Report Flow (output path)

```
Agent has completed a synthesis
  │
  ├──► generate_report(title, synthesis, sources, compound_data) → Report
Server
  │    Returns: {formatted_content, format: "markdown"}
  │
  ├──► save_report("BF-042_analysis.md", content)               → Report
Server
  │    Returns: {path: "data/reports/BF-042_analysis.md"}
  │
  ├──► send_report("researcher@bioforge.com", "BF-042 Analysis") → Report
Server
  │    Returns: {status: "sent", recipient: "researcher@bioforge.com"}
  │
  ▼
Report saved to disk and emailed to researcher
```

Instrumentation Points

Every MCP call should be logged for metric collection. Instrument at the MCP client layer:

```python
@dataclass
class MCPCallLog:
    timestamp: str
    server: str
    tool: str
    input_params: dict
    output: str
    output_size_tokens: int
    latency_ms: float
```

```
    triggered_by: str          # "user" | "agent_reasoning" | "tool_response"
    session_id: str
    call_sequence_number: int  # Position in session call graph
```

This log is the primary data source for ASR, detection rate, and latency overhead metrics.
